

MOTION-BASED TRACKING WITH PAN-TILT-ZOOM CAMERA

ABSTRACT OF THE DISCLOSURE

5 A motion-estimation scheme is provided that employs a combination of motion
estimation and compensation techniques. Low resolution images are computed from two
consecutive image frames, and feature points are determined and matched between the two low
resolution images. Statistical methods are used to estimate the motion in terms of a translation
and rotation of the image plane. Corresponding feature points in the original images are
matched, based on the estimated motion of the low-resolution images. Statistical techniques are
10 then applied to determine a homography matrix that describes the motion between the
corresponding feature points in the original images, and this matrix is used to align the original
images. Differences between the aligned images are identified, to indicate the movement of one
or more objects in the image.
